Regression and time series model selection in small samples

Multivariable methods are computationally complex and generally require the use of a statistical computing package. Multivariable methods can be used to assess and adjust for confounding, to determine whether there is effect modification, or to assess the relationships of several exposure or risk factors on an outcome simultaneously.

Median - Wikipedia

In statistics, sometimes the covariance matrix of a multivariate random variable is not known but has to be estimated.

Estimation of covariance matrices then deals with the question of how to approximate the actual covariance matrix on the basis of a sample from the multivariate distribution. Simple cases, where observations are complete, can be dealt with by using the sample covariance matrix.

Any method will be "sensitive to a small number of cases", meaning that a small study has lower power to detect features of interest than a larger one. With multivariate data, you are not only comparing means -- you are typically estimating a covariance matrix as well, and this requires more data to do with any accuracy.
